

APPARATUS FOR RANDOM ACCESS MEMORY ARRAY SELF-REPAIR

5 This is a Continuation of copending application Serial No. 10/021,614, filed on
12 December 2001, the entire disclosure of which is incorporated herein by reference.

FIELD OF THE INVENTION

10

The present invention relates generally to random access memories (RAM) in integrated circuits and, more particularly, to the test of such circuits and, even more particularly, to their test and repair on-chip.

15

BACKGROUND OF THE INVENTION

Motivated by the desire for both lower cost and higher performance, integrated circuit (IC) technology has moved throughout its history toward building larger and
20 larger circuits comprising more and more devices. The development of random access memory (RAM) integrated circuits have shared in this movement. In the sense of containing a larger number of memory cells where each cell can store one bit, the larger a RAM becomes, the more difficult and expensive it is to test it. Also, the more expensive the cost of a defect in the circuit, as a single defect can result in the loss of the
25 whole chip.

Not only are RAM's fabricated as stand-alone chips, but they are also built embedded as function blocks in other integrated circuits. Such integrated circuits could be designed and produced as standard chips intended for a variety of applications and as application specific integrated circuits (ASIC's).

30 With the size and complexity of modern integrated circuits including RAM's, testing has become an important issue. Size and cost constraints limit the area on the

integrated circuit available for use as wire bonding pads, flip-chip solder bumps, and the like with the resultant effect of limiting access to the various functioning areas of the chip. So, not all functions of the chip are externally available for direct test. Even if connections to some of these areas were available, the long traces and additional external
5 circuitry necessary to access them would introduce signal delays that could render the results of such testing questionable. Thus of necessity, some testing circuitry is now often included on-chip.

On-chip testing also has its share of difficulties as chip area available for testing is limited, as is accessibility to nodes for testing. Delays introduced by trace lengths also
10 continue to be an issue. In addition unless the chip is designed for mass production, the costs associated with design, manufacturing, and test can be prohibitive.

Additional, redundant circuitry is often included in large integrated circuits. Techniques available, as for example laser fusing, permit the removal of defective parts of the IC and its replacement with the redundant part. This process is cost effective, since
15 on average the added cost of the redundant circuitry is less than the cost associated with the yield loss without the additional circuitry. The addition of redundant circuitry is especially valuable for circuits with repeating structure function blocks, such as RAM and other types of memory. In such circuits a limited number of defective cells can be replaced with the redundant cells embedded in the circuitry. Once again, however, unless
20 the chip is designed for mass production, design costs can be prohibitive.

Thus since current techniques for repairing defective cells in RAM function blocks typically require additional processing to correct these defects, there is a need for enhanced means for correcting such defects.

SUMMARY OF THE INVENTION

In one representative embodiment, an electronic circuit for self-repair of a random access memory array is disclosed wherein the random access array has a plurality of memory storage cells, wherein the storage cells are organized into a plurality of slice arrays. The electronic circuit includes a remap register associated with each slice array, a remap selector circuit associated with each slice array, a write selector circuit associated with each slice array, and a read selector circuit associated with each slice array. When a defect is present in one of the memory storage cells of bit-slice, the remap register informs the remap selector circuit of the defect. When, the remap selector circuit is informed that the defect is present, the remap selector circuit instructs the write selector circuit to redirect data intended for storage in the slice array to an adjacent slice array, otherwise, the remap selector circuit instructs the write selector circuit to direct data intended for storage in the slice array to that slice array. When, the remap selector circuit is informed that the defect is present, the remap selector circuit instructs the read selector circuit to redirect data read from the adjacent slice array to the output of slice array, otherwise, the remap selector circuit instructs the read selector circuit to direct data read from the slice array to that slice array.

Other aspects and advantages of the present invention will become apparent from the following detailed description, taken in conjunction with the accompanying drawings, illustrating by way of example the principles of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings provide visual representations which will be used to more fully describe the invention and can be used by those skilled in the art to better understand it and its inherent advantages. In these drawings, like reference numerals
5 identify corresponding elements and:

Figure 1 is a diagram of the architecture of a RAM circuit as described in various representative embodiments consistent with the teachings of the invention.

Figure 2 is a block diagram of an electronic test circuit as described in various
10 representative embodiments consistent with the teachings of the invention.

Figure 3 is another block diagram of the electronic test circuit as described in various representative embodiments consistent with the teachings of the invention.

Figure 4 is a block diagram of circuitry for RAM self-repair as described in various representative embodiments consistent with the teachings of the invention.

Figure 5 is another block diagram of circuitry for RAM self-repair as described
15 in various representative embodiments consistent with the teachings of the invention.

Figure 6 is yet another block diagram of circuitry for RAM self-repair as described in various representative embodiments consistent with the teachings of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

As shown in the drawings for purposes of illustration, the present patent document relates to novel apparatus for the automatic testing of RAM circuits on-chip.

5 Previous circuitry for on-chip testing have required substantial area on the integrated circuit (IC) chip and have been somewhat removed from the tested area introducing propagation delay errors. By locating the circuitry necessary to perform such test in the addressing and input/output blocks of the RAM, these problems have been reduced.

Also, as shown in the drawings for purposes of illustration, the present patent document relates to novel apparatus for the repair of defective RAM circuits. Previous methods for repair of RAM circuits have typically used techniques such as laser repair which permit the removal of defective parts of the integrated circuit chip and then replacement with a redundant part. However, this process is expensive as an additional processing step is involved. By including the circuitry necessary to repair defects in RAM circuits in the input/output blocks of the RAM, this problem has been negated.

In the following detailed description and in the several figures of the drawings, like elements are identified with like reference numerals.

1. RAM Architecture:

20 Figure 1 is a diagram of the architecture of a RAM circuit **105** as described in various representative embodiments consistent with the teachings of the invention. In figure 1, memory storage cells **110**, also referred to herein as storage cells **110** and more concisely as cells **110**, are indicated by small squares. For ease of illustration, only one storage cell **110** is labeled in figure 1.

25 A representative example RAM memory, which is not that shown in figure 1, could comprise logically 416 words with 50 bits of data in each word. Using bit-slice architecture for such an example, a slice of cells is created in which each slice represents one bit of data but it is 416 words. During the design phase, a slice is created that is 416 bits high by one bit wide. This slice is then duplicated 50 times to create the complete array. This methodology creates a very tall and fairly narrow array for this example.

30 By designing the RAM array wherein bits occupying an identical ordinal

positional in nearby words are moved to adjacent horizontal positions, a better aspect ratio for the array can be obtained. In the example of figure 1, each bit-slice **115** contains eight cells **110** in width instead of one. The array now is only 52 words tall with each word still 50 bits wide. Words now, however, are interleaved on the same row. The aspect ratio of the storage array has become more square in the process resulting in a more compact design. A more compact design is preferable as designs that have long traces running vertically between cells could prevent the RAM from functioning properly at the speeds needed.

The RAM circuit **105** of figure 1 includes a RAM array **250**, also referred to herein as a random access memory array **250**, for storing data. The RAM array **250** is divided into sections referred to herein as slice arrays **118** wherein each slice array **118** includes an associated group of memory storage cells **110**

Also shown in figure 1, each bit-slice **115** includes an I/O circuit **130**, as well as the associated slice array **118**. A control and address block **205** comprises a control circuit **210** and an address selection circuit **120**. The control circuit **210** controls test initiation and progress. The address selection circuit **120** enables the selection of memory storage cells **110** for reading and writing of data. In addition, figure 1 shows error detection circuit **230** which has inputs from the I/O circuits **130** and outputs information regarding any errors found during the test to the control circuit **210**.

2. Overview of Self Test Circuitry:

Figure 2 is a block diagram of an electronic test circuit **200** as described in various representative embodiments consistent with the teachings of the invention. The electronic test circuit **200** is also referred to herein as electronic circuit **200**. The electronic test circuit **200** can be built into the address and I/O circuitry of the RAM circuit **105** and can be programmed to test every cell **110** of the RAM array **250** at wafer test, package test, power-up, as well as other times. The electronic test circuit **200** includes the control circuit **210** which controls the flow of the built-in test and the address selection circuit **120** described above. Data is written into and read out of the bit-slices **115** through the I/O circuit **130** of each bit-slice **115**. The results of comparing the data written into the bit-slice **115** and that read out of it is reported to the error detection

circuit **230** which reports those results back to the control circuit **210**.

Figure 3 is another block diagram of the electronic test circuit **200** as described in various representative embodiments consistent with the teachings of the invention. In figure 3, the various components of the test circuit **200** have been interconnected with other circuits normally present in RAM circuits **105**.

3. Detail of Self Test Circuitry - Control Circuit:

The control circuit **210** controls the execution of the test that is performed on the RAM array **250**. As shown in figure 3, the control circuit **210**, has first, second, and third control-circuit inputs **336,337,338** and first, second, third, fourth, and fifth control-circuit outputs **341,342,343,344,345**. While shown as a single line, some of these interconnection may, in fact, be multiple wires.

There are a variety of industry standard tests some of which are referred to as March tests that can be employed to test the RAM array **250**. The March Tests writes preselected patterns in a preselected order into the RAM array **250** and then reads them back out to verify the integrity of the memory storage cells **110**. Different March tests perform their tests in a variety of ways such as whether the test sweeps up or down thru the address space of the RAM array **250** and the number of times that the test is repeated. The test or tests performed, however, could be other than a March test. Regardless of the test performed, it is the control circuit **210** that controls the test.

As the control circuit **210** interacts with the other elements performing the test, various functions and aspects of the control circuit **210** will be discussed in connection with those other elements.

4. Detail of Self Test Circuitry - Test Address Selection Circuit:

The address selection circuit **120** comprises a sequencer **355**, an address multiplexer **365**, a RAM address register **305**, and a comparator **375**.

The control circuit **210** sends a first command **350** to the sequencer **355** at a sequencer control input **356** of the sequencer **355**. The sequencer **355** also has sequencer data input **357** and a sequencer output **358**. The sequencer **355** increments or decrements a memory address **360**, wherein the memory address **360** is the memory address of the

cell **110** selected for test and stored in the RAM address register **305**. The result of the incrementation/decrementation, i.e., the output value of the sequencer **355**, is referred to as an indexed memory address **361**. Incrementation and decrementation can occur in random or in a preselected pattern, the simplest being to increment or decrement by a single address space. The sequencer control input **356** receives various commands from the first control-circuit output **341** of the control circuit **210**. One of these commands is a command to increment. When the increment command is received, the sequencer **355** increments the memory address **360**. Another of these commands is a command to decrement. When the decrement command is received, the sequencer **355** decrements the memory address **360**.

The second control-circuit output **342** transmits a second command **363** which is received by the address multiplexer **365** on an address-multiplexer control input **366**. The address multiplexer **365** also has first, second and third address-multiplexer data inputs **367**, **368**, **369** and an address-multiplexer output **370**. The first address-multiplexer data input **367** receives the incremented/decremented memory address **360** from the sequencer output **358**. The second address-multiplexer data input **368** receives an initial self-test memory address **372**, wherein the initial self-test memory address **372** is the memory address **360** of the first cell **110** selected for test. The third address-multiplexer data input **369** receives RAM memory storage cell **110** addresses during normal operation of the RAM circuit **105**.

When the second command **363** instructs the address multiplexer **365** to select the first address-multiplexer data input **367** as its active input, the address multiplexer **365** transfers contents of the first address-multiplexer data input **367** to the address-multiplexer output **370**. When the second command **363** instructs the address multiplexer **365** to select the second address-multiplexer data input **368** as its active input, the address multiplexer **365** transfers contents of the second address-multiplexer data input **368** to the address-multiplexer output **370**. And, when the second command **363** instructs the address multiplexer **365** to select the third address-multiplexer data input **369** as its active input, the address multiplexer **365** transfers contents of the third address-multiplexer data input **369** to the address-multiplexer output **370**. The address-multiplexer output **370** transfers its contents to the RAM address register **305**.

The comparator **375** receives the contents of the RAM address register **305** on a first comparator input **376**. The comparator **375** also has a first comparator output **377** and a second comparator output **378**. The comparator **375** compares the contents of the RAM address register **305** to the initial self-test memory address **372** and to a final self-test memory address **379**. Final self-test memory address **379** is not shown on any of the drawings. For comparison purposes, both the initial self-test memory address **372** and the final self-test memory address **379** could be, for example, hard wired into the comparator **375**, obtained from the control circuit **210**, or obtained by other means. When the contents of the RAM address register **305** is the same as the initial self-test memory address **372**, the first comparator output **377** is set to indicate that the contents of the RAM address register **305** is the same as the initial self-test memory address **372**, i.e., at the beginning of the test. When the contents of the RAM address register **305** is the same as the final self-test memory address **379**, the second comparator output **378** is set to indicate that the contents of the RAM address register **305** is the same as the final self-test memory address **379**, i.e., the end of test has been reached.

The first control-circuit input **336** receives the contents of the first comparator output **377**. When the first comparator output **377** indicates that the contents of the RAM address register **305** is the same as the initial self-test memory address **372**, the control circuit **210** is so informed at first control-circuit input **336**. When the second comparator output **378** indicates that the contents of the RAM address register **305** is the same as the final self-test memory address **379**, the control circuit **210** is so informed at second control-circuit input **337**. The control circuit **210** may sweep through various test sequences and may repeat those test sequences in various orders before it terminates the test.

An important characteristic of the control circuit **210** is that it is independent of the size of the RAM. It has no knowledge or dependence on the size of RAM addressing. It uses the initial self-test memory address **372** comparison result as reported at the first comparator output **377** and the final self-test memory address **379** comparison result as reported at the second comparator output **378** to tell it where to start and where to stop testing. As a result, once designed the control circuit **210** can be used again and again for different RAM blocks on different integrated circuit chips.

5. Detail of Self Test Circuitry - I/O circuit:

Again in figure 3, various components of the test circuit **200** have been interconnected with other circuits normally present in RAM circuits **105**. During normal operation, operational data **380** is inputted into input register **381** and is written into the slice array **118**. Data is retrieved from the slice array **118** and written into output register **383**.

The I/O circuit **130** comprises components common to the bit-slice **115**, the input register **381** and the output register **383**, as well as a data-in multiplexer **1305**, an inverter **1315**, an input-complement multiplexer **1320**, an output-complement multiplexer **1330**, and an exclusive-OR gate **1340**. All components are present in the I/O circuit **130** regardless of whether tests are being performed or normal data operations are progressing. The data is merely routed according to the operating mode. An input path from the input-complement multiplexer **1320** to the slice array **118** and an output path from the slice array **118** to the output register **383** are shown in figure 3. However, in other embodiments both paths could time share the same transmission path.

The data-in multiplexer **1305** has first and second data-in-multiplexer data inputs **1306,1307**, a data-in-multiplexer control input **1308**, and a data-in-multiplexer output **1309**. The first data-in-multiplexer data input **1306** receives a test data **1310**, and the second data-in-multiplexer data input **1307** receives operational data **380**.

When the control circuit **210** instructs the data-in multiplexer **1305** that it is executing the test, the third control-circuit output **343** transmits a command to the data-in-multiplexer control input **1308** to select the first data-in-multiplexer data input **1306** as the active input and to transfer contents of the first data-in-multiplexer data input **1306** to the data-in-multiplexer output **1309**. Otherwise, the third control-circuit output **343** transmits a command to the data-in-multiplexer control input **1308** to select the second data-in-multiplexer data input **1307** as the active input and to transfer contents of the second data-in-multiplexer data input **1307**, i.e., normal operational data **380**, to the data-in-multiplexer output **1309**. The data-in-multiplexer control input **1308** is preferably two bits wide to accommodate the required commands.

The input register **381** receives data from the data-in-multiplexer output **1309**, and the inverter **1315** receives data from the input register **381**.

The input-complement multiplexer **1320** has first and second input-complement-multiplexer data inputs **1321,1322**, an input-complement-multiplexer control input **1323**, and an input-complement-multiplexer output **1324**. The first input-complement-multiplexer data input **1321** receives data from the input register **381**, and the second
5 input-complement-multiplexer data input **1322** receives the output of the inverter **1315**.

The output-complement multiplexer **1330** has first and second output-complement-multiplexer data inputs **1331,1332**, an output-complement-multiplexer control input **1333**, and an output-complement-multiplexer output **1334**. The first output-complement-multiplexer data input **1331** receives data from the input register **381**, and
10 the second output-complement-multiplexer data input **1332** receives the output of the inverter **1315**.

When the control circuit **210** instructs the input-complement multiplexer **1320** that it is to write the test data **1310**, the fourth control-circuit output **344** transmits a command to the input-complement-multiplexer control input **1323** to select the first
15 input-complement-multiplexer data input **1321** as the active input and to transfer contents of the first input-complement-multiplexer data input **1321** to the input-complement-multiplexer output **1324**. When the control circuit **210** instructs the input-complement multiplexer **1320** that it is to write the inverse test data, the fourth control-circuit output
20 **344** transmits a command to the input-complement-multiplexer control input **1323** to select the second input-complement-multiplexer data input **1322** as the active input and to transfer contents of the second input-complement-multiplexer data input **1322** to the input-complement-multiplexer output **1324**.

During normal operation, i.e., not test, the input-complement multiplexer **1320** transfers operational data **380** stored in the input register **381** from first input-complement-multiplexer data input **1321** to the input-complement-multiplexer output
25 **1324**.

The output-complement multiplexer **1330** and the exclusive-OR gate **1340** are used to compare the data read from the slice array **118** with the expected value as stored in the input register **381**.

30 The output-complement multiplexer **1330** has first and second output-complement-multiplexer data inputs **1331,1332**, the output-complement-multiplexer

control input **1333**, and the output-complement-multiplexer output **1334**. The first output-complement-multiplexer data input **1331** receives data from the input register **381**, and the second output-complement-multiplexer data input **1332** receives the output of the inverter **1315**.

5 When the control circuit **210** instructs the output-complement multiplexer **1330** that it is to select the test data for comparison which is stored in the input register **381**, the fifth control-circuit output **345** transmits command to the output-complement-multiplexer control input **1333** to select the first output-complement-multiplexer data input **1331** as the active input and to transfer contents of the input register **381** to the
10 output-complement-multiplexer output **1334**, otherwise the fifth control-circuit output **345** transmits command to the output-complement-multiplexer control input **1333** to select the second output-complement-multiplexer data input **1332** as the active input and to transfer contents of the inverter output **1315** to the output-complement-multiplexer output **1334**. During normal operation, it is irrelevant whether first output-complement-multiplexer data input **1331** or second output-complement-multiplexer data input **1332**
15 is transferred to the output-complement-multiplexer output **1334**. However, in the representative embodiment, the first output-complement-multiplexer data input **1331** is transferred to the output-complement-multiplexer output **1334**.

 The exclusive-OR gate **1340** has first and second exclusive-OR-gate inputs
20 **1341,1342** and an exclusive-OR-gate output **1343**. The first exclusive-OR-gate input **1341** receives data from the output register **383**, and the second exclusive-OR-gate input **1342** receives the output-complement-multiplexer output **1334**.

 The exclusive-OR gate **1340** is used to compare the data read from the slice array **118**, which is stored in the output register **383** and presented to the first exclusive-OR-gate input **1341** with the expected value which is stored in the input register **381** and presented to the second exclusive-OR-gate input **1342**. When the data in the output register **383** matches that of the expected data the exclusive-OR gate **1340** outputs a binary zero to the exclusive-OR-gate output **1343** indicating a success. Otherwise, the exclusive-OR gate **1340** outputs a binary one to the exclusive-OR-gate output **1343**
25 indicating a failure.
30

6. Detail of Self Test Circuitry - Error detection circuit:

The error detection circuit **230** has a plurality of error detection circuit inputs **231** and a single error detection circuit output **232**. The output of each exclusive-OR-gate output **1343** is transferred to its associated error detection circuit input **231**. The error
5 detection circuit **230** combines the results of the exclusive-OR gates **1340** for every bit-slice **115** and reports the result to the control circuit **210** via the error detection circuit output **232** to the third control-circuit input **338**.

7. Redundant RAM Model:

Figure 4 is a block diagram of circuitry for RAM self-repair as described in various representative embodiments consistent with the teachings of the invention. In figure 4, the RAM array **250** is divided into bit-slices **115**, each of which includes its associated slice array **118** and I/O circuit **130** as previously stated. The RAM array **250** also comprises a redundant slice **410**. Should the RAM array **250** not have any defects,
15 the redundant slice **410** is not used. However, should a defect be encountered, data flow is routed around the bit-slice **115** containing the defect, and the redundant slice **410** is used in its place. The following error types, which are the five most common defect mechanisms, can be corrected using the techniques disclosed herein: (1) single bit, (2) paired bit (two adjacent bits within the same slice), (3) single column, and (4) paired
20 column (two adjacent columns within the same slice), and (5) slice. Essentially any and all defects occurring in the same slice can be repaired as repair occurs via a remapping of slices.

In the example of figure 4, the bit-slice **115** corresponding to k-th bit-slice **115** contains a defect **415** which is corrected by rerouting bit-slice I/O for all bit-slices **115**
25 to the right of and including the bit-slice **115** for the k-th bit-slice **115**. Each bit-slice comprises two I/O paths, a normal bit-slice I/O path **420** and a alternate bit-slice I/O path **425**. Bit-slices **115** to the left of the bit-slice **115** containing the defect **415** utilize their normal bit-slice I/O paths **420** for input/output of those bit-slices **115**. The bit-slice **115** containing the defect **415** and all bit-slices **115** to the right of that bit-slice **115** utilize
30 their alternate bit-slice I/O paths **425** for input/output of those bit-slices **115**. Thus, all bit-slices **115** to the right of the bit-slice **115** containing the defect **415**, as well as the

redundant slice **410**, are mapped to the I/O circuit **130** to their immediate left.

8. Overview of Redundant RAM Circuitry:

Figure 5 is another block diagram of circuitry for RAM self-repair as described in various representative embodiments consistent with the teachings of the invention. As in figure 4, it is assumed that a defect occurs in the k-th slice array **118**. In such case, a remap register **515** for the k-th bit-slice **115** informs remap selector circuit **520** to redirect data for the k-th bit-slice **115** to the (k-1)-th bit-slice **115** for storage in the (k-1)-th slice array **118**. The remap selector circuit **520** in turn instructs a write selector circuit **505** for the k-th bit-slice **115** to write the data for the k-th bit-slice **115** into the (k-1)-th slice array **118**.

The remap register **515** for the k-th bit-slice **115** informs remap selector circuit **520** to redirect data read from the (k-1)-th slice array **118** to the k-th bit-slice **115** for transfer out. The remap selector circuit **520** in turn instructs a read selector circuit **510** for the k-th bit-slice **115** to read the data for the k-th bit-slice **115** from the (k-1)-th slice array **118**.

Figure 6 is yet another block diagram of circuitry for RAM self-repair as described in various representative embodiments consistent with the teachings of the invention. Figure 6 shows various circuitry from previous figures. In particular this circuitry includes (1) the input register **381**, (2) the input-complement multiplexer **1320**, (3) the output-complement multiplexer **1330**, (4) the slice array **118**, (5) the output register **383**, and (6) the exclusive-OR gate **1340**.

In addition to the circuitry used for normal RAM read/write functions and defect detection, circuitry necessary for defect repair is as follows: (1) a write multiplexer **605**, (2) a read multiplexer **610**, (3) the remap register **515**, and (4) an OR gate **620**. The write multiplexer **605** has first and second write-multiplexer inputs **606,607**, a write-multiplexer control input **608**, and a write-multiplexer output **609**. The read multiplexer **610** has first and second read-multiplexer inputs **611,612**, a read-multiplexer control input **613**, and a read-multiplexer output **614**. The remap register **515** has a remap-register input **616** and a remap-register output **617**. The OR gate **620** has first and second OR-gate inputs **621,622** and an OR-gate output **623**.

As long as no defects **415** occur to the left of or in bit-slice “k” **115** in figure 6, the write multiplexer **605** is enabled so as to write operational data **380** from the input register **381** into its associated bit-slice **115** through input-complement multiplexer **1320**. The function of input-complement multiplexer **1320** was explained in the discussion of figure 3. Also, the read multiplexer **610** is enabled so as to read data stored in the associate RAM bit-slice **115** into the output register **383** associated with that RAM bit-slice **115**. When the output of the OR gate **620**, identified as OR-gate output **623**, is a binary zero, both inputs to the OR gate **620**, identified as first OR-gate input **621** and second OR-gate input **622**, are binary zero. The binary zero at the first OR-gate input **621** indicates that no defects were found in any of the bit-slices **115** to the left of the k-th bit-slice **115**, and the binary zero at the second OR-gate input **622** indicates that the k-th bit-slice **115** is free of defects **415**. The fact that no defects **415** were found in the k-th bit-slice **115** during the test phase is recorded in the remap register **515** by storing a binary zero in it.

If, however, a defect **415** occurs in the k-th bit-slice **115** that fact is recorded in remap register **515**. The fact that defect **415** is present in the k-th bit-slice **115** would have been detected during the test phase. In a representative application, the remap register **515** then would have a binary one value stored in it. The OR-gate output **623** then becomes a binary one which switches the k-th write multiplexer **605** to write the value from the (k+1)-th input register **381** into the memory of the k-th bit-slice **115**. This action is, however, of no consequence as any data in the k-th bit-slice **115** will be ignored since it is known to have the defect **415**. Of more importance is the fact that the read multiplexer control input switches the read multiplexer **610** for the k-th bit-slice **115** to read data from the (k-1)-th bit-slice **115** into the output register **383** for the k-th bit-slice **115** instead of the (k-1)-th bit-slice **115**.

Since the OR-gate output **623** for the k-th bit-slice **115** provides the first OR-gate input **621**, the OR-gate output **623** for the (k-1)th bit-slice **115** becomes a binary one indicating that the defect **415** occurred in a bit-slice **115** prior to that of the (k-1)th bit-slice **115**. This value for the output of the OR gate **620** for the (k-1)th bit-slice **115** switches the write multiplexer **605** for the (k-1)-th bit-slice **115** to write the operational data **380** from the input register **381** of the k-th bit-slice **115** to be written into the

memory of the (k-1)-th bit-slice **115**.

In a manner similar to that described above, the data stored in the (k-2)th bit-slice **115** will be read out by the read multiplexer **610** of the (k-1)-th bit-slice **115** into the output register **383** of the (k-1)-th bit-slice **115**. Thus, all remapping of data for both read
5 and write functions is programmed into the remap registers **515** when the RAM array **250** is tested.

9. Concluding Remarks:

In representative embodiments of the apparatus described in the present patent
10 document, techniques for the on-chip testing of RAM circuits on-chip are disclosed. Present techniques for on-chip testing do not require substantial area on the chip and are inherently located closer to the tested area which reduces propagation delay errors. By locating the circuitry necessary to perform such test in the addressing and input/output blocks of the RAM, these advantages have been obtained.

15 In other representative embodiments of the apparatus described in the present patent document, techniques for the soft repair of defective RAM circuits are disclosed. Present techniques for repair of RAM circuits do not use techniques such as laser repair in the removal of defective parts of the IC and its replacement with a redundant part. The present process is inexpensive and no additional processing steps are involved. By
20 including the circuitry necessary to repair defects in RAM circuits in the input/output blocks of the RAM, these advantages have been obtained.

While the present invention has been described in detail in relation to representative embodiments thereof, the described embodiments have been presented by way of example and not by way of limitation. It will be understood by those skilled in
25 the art that various changes may be made in the form and details of the described embodiments resulting in equivalent embodiments that remain within the scope of the appended claims.
